Ann Based Distribution Static Compensator For Power Quality Improvement With Linear Sinusoidal Tracer Control Algorithm

Mr. K.Lakshmi Narayana, Mr. K.V.V.Satya Narayana

Abstract- In this paper an ANN based DSTATCOM is proposed for reactive power compensation, harmonics elimination, zero voltage regulation, power factor correction, neutral current compensation and unbalance caused by various loads in the distribution system. Various configurations and topologies of DSTATCOM are used for reduction of distortions with acceptable level of performance according to the IEEE-519 standard with an optimal use of dc bus of a voltage source converter (VSC) used as DSTATCOM and in cost-effective manner. This paper presents the effectiveness of adaptive theory based Improved Linear Sinusoidal Tracer control algorithm (ILST). This algorithm is used for extraction of load fundamental active and reactive power components of currents which are used for estimation of reference source currents. The effectiveness of the proposed system designed and simulated under the MATLAB / SIMULINK environment. Simulation results of this system represent the performance of the Improved Linear Sinusoidal Tracer control algorithm (ILST).

Keywords- DSTATCOM, ANN, voltage source converter (VSC), adaptive theory based Improved Linear Sinusoidal Tracer (ILST).

I. INTRODUCTION

In the present scenario of AC transmission network, the mitigation of power quality problems is the major challenge due to increase of power electronic devices [1]. Static power converters such as rectifiers, large number of low-power electronic-based appliances, induction heating, switch mode power supplies, adjustable speed drives, electric traction, cyclo-converters etc. are nonlinear loads that generate considerable distortions in the ac mains current and causing power quality problems [2, 3]. A control algorithm should have good detection accuracy, wide range of adjustment of internal parameters, stability performance, and fast dynamic response. The performance of DSTATCOM depends largely on the right and accurate real-time detection of harmonics and reactive currents etc. Sawant and Chandorkar have described multifunction active filter using instantaneous p-q-r theory. One of the new applications of active filter is described by Crosier and Wang [7] where it is applied for grid connected electric vehicle charging station. Buenoet al. [8] have described application of active filter for railway supply system. DSTATCOM (Distribution Static Compensator) is also used for power quality improvement in pico-hydro based power generation [9], isolated wind power generation system etc. Singh has described different configurations of DSTATCOM such as three leg, four leg and characteristics of nonlinear loads. Active filters needs to detect the total distortion current outside the fundamental active source component of currents. A widely used method is the detection algorithm based on the theory of instantaneous reactive power.

Effective use of DSTATCOM is directly related to the design of power circuit components such as dc-bus capacitor, interfacing inductors, and VSC, control algorithm used for the estimation of reference source currents with increased speed and less calculation, switching scheme for gating pulses, and stability issues of a designed control algorithm [18]–[27]. An area of adaptive control provides an automatic adjustment of the controller gains and parameters in real time, in order to achieve a desired level of performance. It provides an automatic tuning procedure in a closed loop for the controller parameters. Characteristics of these control algorithms are the ability to extract necessary information from real online data in order to tune the controller, and also used for grid synchronization [28], [29].

In synchronized filtered-x algorithm-based adaptive control [30], a proportional regulator is used to improve the dynamic performance of the system because it needs high gain at only fundamental and harmonic frequencies of the load currents. Thus, it is suitable only for filtering harmonics currents from one or more specified harmonic-producing loads. An algorithm based on adaptive interference canceling theory [31] requires a continuously updating closed-loop system, and its operating characteristics are almost independent of the parameter variations of the elements due to temperature or oldness of system. It requires a band-pass filter and an integrator where the performance of a filter depends upon selected cutoff frequencies. An iterative algorithm for adaptive harmonic detection [32] proposed by Zeng and Li is based on coherent average estimation (CAE). CAE is used to detect a weak periodic signal. The method is used in periodic signal to filter out undesirable components and extract the useful signals. It requires knowledge and count of cycles. If this information is correctly known, then a single cycle of some signals can be taken for process.

An adaptive control algorithm based on an artificial immune system [33] is developed based on immune feedback principles for unknown, random, and severe disturbances. An important characteristic of this adaptive controller is that the original optimal controller parameters are restored after clearing the disturbances and return to the normal condition. But, its performance depends upon the effect of disturbances and action of its modifier. Mojiri et al.
An error in the linear sinusoid tracer algorithm is affected by the high-order harmonics. Thus, this algorithm is not able to detect harmonics current accurately. For removal of this limitation, a low-pass filter (LPF) is used and this modification is named as an adaptive theory-based improved linear sinusoid tracer (ILST) where source current and reference current both are tracing each other without any change even at unbalance loads. Its structure is simple. Theoretical study of this algorithm for the estimation of fundamental signal is reported by Du and Su [37]. However, it has been limited to the simulation study of extraction of signals of single-phase loads. In an adaptive theory-based improved linear sinusoidal tracer control algorithm is implemented on a DSTATCOM for the extraction of load currents’ fundamental components in three phase consumer loads. It is used for power factor correction (PFC) and ZVR along with load balancing and harmonics elimination.

Good detection accuracy, wide range of adjustment of internal parameters, stability performance, and fast dynamic response are the main features of this control algorithm. Internal parameters of this algorithm have clear physical understanding and easy adjustable to optimal value, which show the simplicity of this algorithm. Frequency- and time-domain characteristics of the ILST are not affected due to external environment changes.

Detection accuracy and speed of the dynamic response can be tuned after adjusting algorithm internal parameters. For the desired frequency and bandwidth, the ILST control algorithm is able to extract instantaneous value and the amplitude of a sinusoidal by least-squares error, gradient descent method, and rotation transform. To achieve an ideal performance, the value of constant $p$ is equal to the source frequency $\omega_0$ and the band width $\gamma$ should be an optimal value. In this algorithm, extracted reference source currents exactly follow the actual source currents during steady-state as well as dynamic conditions. For this reason, three-phase source currents have smooth variation during load perturbations. This control algorithm is implemented on a DSTATCOM for compensation of linear and nonlinear loads.

**II. SYSTEM CONFIGURATION**

A VSC-based DSTATCOM is shown in Fig. 1. It is connected to a three-phase AC mains feeding three-phase linear/nonlinear loads with grid source impedance $Z_s$. For reducing ripple in compensating currents, interfacing inductors $L_f$ are used at an AC side of the VSC.A zig-zag/three single-phase transformers used for neutral current compensation. A three-phase series combination of capacitor $(C_a, C_b, C_c)$ and a resistor $(R_a, R_b, R_c)$ represent the passive ripple filter, which is connected at point of common coupling (PCC) for filtering the high frequency switching noise of the VSC. Generally, the same value of series-connected capacitor and resistance as a ripple filter is used in all the three phases. The DSTATCOM currents $i_{abc}$ are injected as required compensating currents to cancel the reactive power components and harmonics of the load currents so that loading due to reactive power component/harmonics is reduced on the distribution system. The rating of the insulated gate bipolar transistor (IGBT) switches of the VSC is based on the voltage and current rating for the required compensation. For a considered load of 50 kVA (0.8 lagging), the compensator data are given in Appendix A. The rating of the VSC for the reactive power compensation/harmonics elimination is found to be 35 kVA (approximate 15% higher than the reactive power from rated value). The designed value of different auxiliary components of DSTATCOM such as interfacing ac inductors, dc-bus voltage, and value of dc-bus capacitor are also given in Appendix A.

---

![Fig. 1. Schematic diagram of VSC-based DSTATCOM](image_url)
The average amplitude of fundamental active power components \( I_{LPA} \) is estimated using amplitude sum of three-phase load active power components \( (I_{LPA}, I_{LPB}, \text{and } I_{LPC}) \) divided by three for load balancing. First-order low-pass filters are used to separate the low-frequency components. Mathematically, it is expressed as:

\[
I_{LPA} = \frac{(I_{LPA} + I_{LPB} + I_{LPC})}{3}
\]

Similarly, amplitudes of reactive power components \( (I_{LQA}, I_{LQB}, \text{and } I_{LQC}) \) of fundamental load currents are extracted at the zero crossing of the quadrature unit template phase of PCC voltages using zero-crossing detector (ZCD2) and signal and hold logic (SCH2). An output signal of SCH2 is known as the amplitude of fundamental reactive power components of load current. The average amplitude of the fundamental reactive power component \( I_{LQA} \) estimated using load fundamental reactive power current components \( I_{LQA}, I_{LQB}, \text{and } I_{LQC} \) low-pass filter is used to extract its smooth or ripple-free component. Mathematical expression of the average amplitude of the fundamental reactive power current component \( I_{LQA} \) is given as:

\[
I_{LQA} = \frac{(I_{LQA} + I_{LQB} + I_{LQC})}{3}
\]

Fig. 2(b) shows the subsection of an adaptive theory-based ILST control algorithm. The transfer function \( G_1(s) \) of a low-pass filter is as:

\[
G_1(s) = \frac{1}{\tau s + 1}
\]

Where \( \tau \) is the time constant of a L.P.F. and it is greater than zero. The transfer function in Fig. 2(b) is terms of phase ‘c’, extracted fundamental current \( I_{LCA} \) and load current \( I_{LCA} \) can be written as:

\[
C(s) = \frac{I_{LCA}}{I_{LCA}} = \frac{G(s)}{1 + G(s)H(s)}
\]

Where forward path transfer function:

\[
G(s) = \frac{\psi}{\tau s^2 + (\tau + 1)s + \rho + \psi}
\]

and feedback transfer function \( H(s) = 1 \).

The characteristic equation of the transfer function is written as:

\[
\tau s^2 + (\tau + 1)s + (\rho + \psi) = 0
\]

Where \( \tau \) is time constant of a low-pass filter, \( \rho \) is power frequency, \( \psi \) is frequency band of a band-pass filter. Stability of characteristic equation is analyzed using a Rough–Hurwitz criterion. Details of this analysis is given in the Appendix B. Reference dc-bus voltage \( v_{qd}^\text{ref} \) and sensed dc-bus voltage \( v_{qd} \) of a VSC are compared and error in dc-bus voltage at the kth sampling instant is expressed as:

\[
v(k) = v_{qd}^\text{ref}(k) - v_{qd}(k)
\]

This dc-bus voltage error \( v(k) \) is fed to a proportional–integral (PI) regulator whose output is required for maintaining dc-bus voltage of the DSTATCOM. Its output at the kth sampling instant is given as:

\[
l_{dp}(k) = l_{dp}(k - 1) + k_{pd}[v(k) - v(k - 1)]k_{id}v_{q}(k)
\]

Where \( k_{pd} \text{ and } k_{id} \) are the proportional and integral gain constants of the de bus PI controller. \( v(k) \) and \( v(k - 1) \) are the dc-bus voltage errors at kth and (k - 1)th instants.
and $I_{dp}(k)$ and $I_{dp}(k-1)$ are the amplitudes of the active power component of the fundamental reference current at kth and (k–1)th instants. The amplitude of active power current components of the reference source current $I_{sq}$ is calculated by an addition of output of dc-bus PI controller $I_{np}$ and an average magnitude of the load active power component of currents $I_{npA}$ as:

$$I_{sq} = I_{np} + I_{npA}$$  \hspace{1cm} (11)

A reactive power component of reference source currents is required for the operation of DSTATCOM in the ZVR mode. In the ZVR mode, source currents are slightly leading from the ac mains voltages because extra leading reactive power component is required for regulating the voltage at PCC. It is zero in the operation of DSTATCOM in the PFC mode. The voltage error between reference PCC voltage $v_t^*$ and its sensed value $v_ks$ is fed to the PCC voltage PI controller. The voltage error $v_{te}$ of ac voltage at the kth sampling instant is given as:

$$v_{te}(k) = v_t^*(k) - v_t(k)$$  \hspace{1cm} (12)

The output of the PCC voltage PI controller $I_{sq}$ for maintaining PCC terminal voltage to a constant value at the kth sampling instant is given as:

$$I_{sq}(k) = I_{sq}(k-1) + k_v[v_{te}(k-1) + k_i v_{eo}(k)]$$  \hspace{1cm} (13)

Where $I_{sq}(k)$ is a part of the reactive power component of source current and it is named as $I_{sq}$, $I_{np}$ and $k_v$ are the proportional and integral gain constants of the PCC voltage PI controller. Gains of PI controller for dc-bus voltage: $k_{np} = 2.4$, $k_{nt} = 1.54$; gains of the PCC voltage PI controller: $k_{vt} = 3.1$, $k_{vt} = 0.95$. The amplitude of reactive power current components of the reference source current $I_{sq}$ is calculated by subtracting average load reactive currents $I_{qA}$ from the output of voltage PI controller $I_{sq}$ as:

$$I_{qA} = I_{sq} - I_{qA}$$  \hspace{1cm} (14)

Three-phase reference source active and reactive power components of currents are determined using amplitude of three phases (a, b, and c) load active and reactive power current components, PCC voltages in-phase, and quadrature voltage unit templates as:

$$i_{sap} = I_{qA}w_{pa}, \quad i_{sbp} = I_{qA}w_{pb}, \quad i_{scp} = I_{qA}w_{pc}$$  \hspace{1cm} (15)

$$i_{sao} = I_{qA}w_{qa}, \quad i_{sbo} = I_{qA}w_{qb}, \quad i_{soc} = I_{qA}w_{qc}$$  \hspace{1cm} (16)

Reference source currents ($i_{sa}^*, i_{sb}^*$, and $i_{sc}^*$) are estimated by the addition of reference active and reactive power components of currents as:

$$i_{sa}^* = i_{sap} + i_{sao}, \quad i_{sb}^* = i_{sbp} + i_{sbo}, \quad i_{sc}^* = i_{scp} + i_{soc}$$  \hspace{1cm} (17)

$$i_{sa} = i_{sa}^* + i_{saq}, \quad i_{sb} = i_{sb}^* + i_{sbb}$$  \hspace{1cm} (18)

The sensed source currents ($i_{sa}$, $i_{sb}$, and $i_{sc}$) and these reference source currents ($i_{sa}^*$, $i_{sb}^*$, and $i_{sc}^*$) are compared for respective phases and each phase current error is amplified using PI current regulators and their outputs are compared with a carrier signal of 10 kHz to generate the gating signals for IGBT switches of VSC used as DSTATCOM.

In this paper ANN controller is used instead of PI controller to improve the results and decrease the %THD.

**B. ANN controller:**

An ANN is essentially a cluster of suitably interconnected nonlinear elements of very simple form that possess the ability of learning and adaptation. These networks are characterised by their topology, the way in which they communicate with their environment, the manner in which they are trained and their ability to process information. Their ease of use, inherent reliability and fault tolerance has made ANNs a viable medium for control. An alternative to fuzzy controllers in many cases, neural controllers share the need to replace hard controllers with intelligent controllers in order to increase control quality. A feed forward neural network works as compensation signal generator. This network is designed with three layers. The input layer with seven neurons, the hidden layer with 21 and the output.

The training algorithm used is Levenberg–Marquardt Backpropagation (LMBP). Training is given as follows:-

- net=newff(minmax(P),[7,21,3],
- {‘tansig’,’tansig’,’purelin’},’trainlm’);
- net.trainParam.show =50;
- net.trainParam.lr = .05;
- net.trainParam.mc = 0.95;
- net.trainParam.Lr_inc = 1.9;
- net.trainParam.Lr_dec = 0.15;
- net.trainParam.epoch = 1000;
- net.trainParam.goal = 1e-6;
- [net,tr]=train(net,P,T);
- a=sim(net,P);
- gnet=net,test;

**IV. SIMULATION RESULTS**

In the ZVR mode, the amplitude of PCC voltage is regulated to the reference amplitude by injecting the leading reactive power components. Fig. 3 shows the dynamic performance of the DSTATCOM used for reactive power compensation to achieve ZVR and load balancing under linear loads (at $t = 1.35$–1.45 s). The performance indices are as PCC phase voltages ($v_t$), balanced source currents ($i_s$), load currents ($iLa, iLb$, and $iLc$, compensator currents ($iCa, iCb$, and $iCc$), amplitude of voltages at PCC ($v_t$), and dc-bus voltage ($vdc$) under time-varying linear loads. The performance of DSTATCOM is also studied under uncontrolled rectifier-based nonlinear loads. The dynamic performance of DSTATCOM in terms of waveforms and harmonics spectra of phase “a” voltage at PCC $vsa$, source current $isa$, and load current $iLa$ are shown in Figs. 4 and 5(a)–(c), respectively.

THDs of the phase “a” at PCC voltage, source current, and load current are observed 3.14%, 3.27%, and 26.15%, respectively. Three-phase PCC voltages are regulated up to rated value. The amplitude of three-phase voltage is regulated from $330.36$ to $338.70$ V and $335.5$ to $338.8$ V at linear and nonlinear loads, respectively. It may be seen that the THD of the source current and PCC voltage are within IEEE519-1992 standard limit of 5%. PCC voltage is also regulated even at unbalanced loads. Table I shows the

V. CONCLUSION

A three-phase DSTATCOM has been implemented with ANN controller for compensation of linear and nonlinear loads using an ILST control algorithm. The ILST control algorithm has been used for the extraction of reference source currents to generate the switching pulses of DSTATCOM. Various functions of DSTATCOM such as reactive power compensation, harmonic elimination, and...
load balancing have been demonstrated in ZVR mode. From these results, it is concluded that DSTATCOM and its control algorithm with ANN controller have been found suitable for time-varying loads. PCC and DC bus voltages of the DSTATCOM have also been regulated to reference values under unbalanced loads.
